The Madagascar day gecko, Jane, can be extremely difficult to find. That's on purpose! Madagascar day geckos are bright green, which matches perfectly with the leaves in their tropical rainforest habitats, giving them an excellent form of camouflage.

Madagascar day geckos are native to the island of Madagascar off the east coast of Africa. They are also one of the few gecko species that are awake during the day, or diurnal. In their rainforest habitats, day geckos eat primarily insects and occasionally eat mashed up fruit. They have special adhesive scales called lamellae on their toes that allows them to cling to surfaces like glass!

- They have a large range of vocalizations ranging from hisses to squeaks to barks!
- Madagascar day gecko eggs that are incubated at 80-85 degrees become males, while eggs incubated at 77-81 degrees will be females.

Color in this Madagascar day gecko in their rainforest home!

The scales of many gecko species are colored in ways that allow them to blend in to the world around them! Draw an environment around this gecko and then draw a pattern on them that allows them to camouflage with their surroundings!
